Lecture 10: Deep Q-learning

Zhi Wang

Department of Control Science and Intelligent Engineering Nanjing University

2025/04/21

Contents and Goals

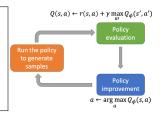

- How we can make Q-learning work with deep networks
 - Use replay buffers, separate target networks
- Tricks for improving Q-learning in practice
 - Double Q-learning, multi-step Q-learning
- Continuous Q-learning methods
- Goals
 - Understand how to implement Q-learning so that it can be used with complex function approximators
 - Understand how to extend Q-learning to continuous actions

Table of Contents

- Q-learning with deep neural networks
 - Problem 1: Correlated samples Solution 1: Replay buffers
 - Problem 2: Moving target Solution 2: Target networks
- Deep deterministic policy gradient (DDPG)
 - Continuous action space
 - Approximate the optimal policy using another network
- 3 Extensions
 - Double Q-learning
 - Multi-step returns
 - Practical tips and examples

Review: Fitted Q-iteration (FQI)

- Full fitted Q-iteration algorithm. Loop:
 - 1. collect dataset $\{(s_i, a_i, r_i, s_i')\}$ using behavior policy π loop for K iterations:
 - 2. set $y_i \leftarrow r_i + \gamma \max_{a_i'} Q_{\phi}(s_i', a_i')$
 - 3. set $\phi \leftarrow \arg\min_{\phi} \sum_{i} ||Q_{\phi}(s_i, a_i) y_i||^2$
- Online fitted Q-iteration algorithm. Loop:
 - 1. observe one sample (s_i, a_i, r_i, s_i') using behavior policy π
 - 2. set $y_i \leftarrow r_i + \gamma \max_{a_i'} Q_{\phi}(s_i', a_i')$
 - 3. set $\phi \leftarrow \phi \alpha \frac{dQ_{\phi}(s_i, a_i)}{d\phi} (Q_{\phi}(s_i, a_i) y_i)$

Problem 1: Correlated samples in MDPs

- Online fitted Q-iteration algorithm. Loop:
 - 1. take some action a_i observe (s_i, a_i, r_i, s'_i)
 - 2. set $y_i \leftarrow r_i + \gamma \max_{a_i'} Q_{\phi}(s_i', a_i')$
 - 3. set $\phi \leftarrow \phi \alpha \frac{\mathrm{d}Q_{\phi}(s_i, a_i)}{\mathrm{d}\phi} (Q_{\phi}(s_i, a_i) y_i)$
- these samples are correlated!
- Fitted Q-iteration is not gradient descent!

$$\phi \leftarrow \phi - \alpha \frac{\mathrm{d}Q_{\phi}(s_i, a_i)}{\mathrm{d}\phi} \left(Q_{\phi}(s_i, a_i) - \underbrace{\left(r_i + \gamma \max_{a_i'} Q_{\phi}(s_i', a_i') \right)}_{\text{no gradient through target value!}} \right)$$

Z Wang (NJU) Deep Q-learning 2025/04/21 5 / 58

Review: Supervised learning vs. Sequential decision-making

Supervised learning

- Samples are independent and identically distributed (i.i.d.)
- Given an input, map an optimal output

Reinforcement learning

- Samples are not i.i.d., temporally correlated
- Given an initial state, find a sequence of optimal actions

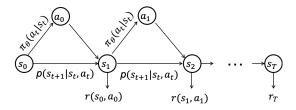

Correlated samples in online Q-learning

- Online fitted Q-iteration algorithm. Loop:
 - 1. take some action a_i , observe (s_i, a_i, r_i, s_i')

2. set
$$\phi \leftarrow \phi - \alpha \frac{dQ_{\phi}(s_i, a_i)}{d\phi} \left(Q_{\phi}(s_i, a_i) - \left(r_i + \gamma \max_{a_i'} Q_{\phi}(s_i', a_i') \right) \right)$$

- sequential states are strongly correlated
- target value is always changing

Correlate samples

- Full fitted Q-iteration algorithm. Loop:
 - 1. collect dataset $\{(s_i, a_i, r_i, s_i')\}$ using behavior policy π loop for K iterations:
 - 2. set $y_i \leftarrow r_i + \gamma \max_{a_i'} Q_{\phi}(s_i', a_i')$
 - 3. set $\phi \leftarrow \arg\min_{\phi} \sum_{i}^{i} ||Q_{\phi}(s_i, a_i) y_i||^2$

- Online fitted Q-iteration. Loop:
 - 1. take some action a_i , observe (s_i, a_i, r_i, s_i')
 - 2. set $y_i = r_i + \gamma \max_{a'_i} Q_{\phi}(s'_i, a'_i)$
 - 3. set $\phi \leftarrow \phi \alpha \frac{dQ_{\phi}(s_i, a_i)}{d\phi} (Q_{\phi}(s_i, a_i) y_i)$

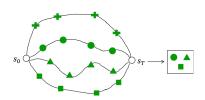

special case with K=1, and one gradient step

How to reduce the correlation between samples?

- Samples in a single episode:
 - temporally correlated

- Samples from different episodes:
 - i.i.d

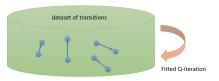

9/58

Replay buffers: store the data/transitions

- Full fitted Q-iteration algorithm. Loop:
 - 1. collect dataset $\{(s_i, a_i, r_i, s_i')\}$ using behavior policy π loop for K iterations:
 - 2. set $y_i \leftarrow r_i + \gamma \max_{a_i'} Q_{\phi}(s_i', a_i')$
 - 3. set $\phi \leftarrow \arg\min_{\phi} \sum_{i} ||Q_{\phi}(s_i, a_i) y_i||^2$

- any behavior policy π will work!
- just load data from a buffer here
- ullet still use K=1 and one gradient step

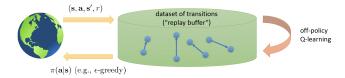

Q-learning with a replay buffer

- Loop:
 - 1. sample a batch $\{(s_j, a_j, r_j, s_j')\}$ from buffer \mathcal{B}

2.
$$\phi \leftarrow \phi - \alpha \sum_{i} \frac{dQ_{\phi}(s_j, a_j)}{d\phi} \left(Q_{\phi}(s_j, a_j) - \left(r_j + \gamma \max_{a'_j} Q_{\phi}(s'_j, a'_j) \right) \right)$$

- Step 1: samples are no longer correlated if they come from different episodes
- Step 2: use multiple samples in the batch for low-variance gradient
- Question: Where does the data come from?
 - Need to periodically feed the replay buffer

Full Q-learning with a replay buffer

- Loop:
 - 1. collect dataset $\{(s_i, a_i, r_i, s_i')\}$ using behavior policy, add it to \mathcal{B} loop for K iterations:
 - 2. sample a batch $\{(s_j, a_j, r_j, s_j')\}$ from buffer \mathcal{B}

3.
$$\phi \leftarrow \phi - \alpha \sum_{j} \frac{\mathrm{d}Q_{\phi}(s_{j}, a_{j})}{\mathrm{d}\phi} \left(Q_{\phi}(s_{j}, a_{j}) - \left(r_{j} + \gamma \max_{a'_{j}} Q_{\phi}(s'_{j}, a'_{j}) \right) \right)$$

• K=1 is common, though larger K is more efficient

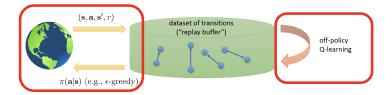

Table of Contents

- Q-learning with deep neural networks
 - Problem 1: Correlated samples Solution 1: Replay buffers
 - Problem 2: Moving target Solution 2: Target networks
- 2 Deep deterministic policy gradient (DDPG)
 - Continuous action space
 - Approximate the optimal policy using another network
- 3 Extensions
 - Double Q-learning
 - Multi-step returns
 - Practical tips and examples

Problem 2: Moving target in the Bellman equation

- Online fitted Q-iteration algorithm. Loop:
 - 1. take some action a_i observe (s_i, a_i, r_i, s_i')
 - 2. set $y_i \leftarrow r_i + \gamma \max_{a_i'} Q_{\phi}(s_i', a_i')$
 - 3. set $\phi \leftarrow \phi \alpha \frac{\mathrm{d}Q_{\phi}(s_i, a_i)}{\mathrm{d}\phi} (Q_{\phi}(s_i, a_i) y_i)$
- Samples are correlated: solved by a replay buffer
- Fitted Q-iteration is not gradient descent!
 - ullet Target value changes when the Q-network ϕ is updated!

$$\phi \leftarrow \phi - \alpha \frac{\mathrm{d}Q_{\phi}(s_i, a_i)}{\mathrm{d}\phi} \left(Q_{\phi}(s_i, a_i) - \underbrace{\left(r_i + \gamma \max_{a_i'} Q_{\phi}(s_i', a_i') \right)}_{\text{no gradient through target value!}} \right)$$

Z Wang (NJU) Deep Q-learning 2025/04/21 14 / 58

The moving target

- Full Q-learning with a replay buffer. Loop:
 - 1. collect dataset $\{(s_i, a_i, r_i, s_i')\}$ using behavior policy, add it to $\mathcal B$ loop for K iterations:
 - 2. sample a batch $\{(s_j,a_j,r_j,s_j')\}$ from buffer ${\cal B}$

3.
$$\phi \leftarrow \phi - \alpha \sum_{j} \frac{dQ_{\phi}(s_j, a_j)}{d\phi} \left(Q_{\phi}(s_j, a_j) - \left(\frac{r_j + \gamma \max_{a'_j} Q_{\phi}(s'_j, a'_j)}{a'_j} \right) \right)$$

one gradient step, moving target

- Full fitted Q-iteration algorithm. Loop:
 - 1. collect dataset $\{(s_i, a_i, r_i, s_i')\}$ using behavior policy π loop for K iterations:
 - 2. set $y_i \leftarrow r_i + \gamma \max_{a'_i} Q_{\phi}(s'_i, a'_i)$
 - 3. set $\phi \leftarrow \operatorname*{arg\,min}_{\phi} \sum_{i} \left| \left| Q_{\phi}(s_{i}, a_{i}) y_{i} \right| \right|^{2}$

perfectly well-defined, stable regression

Solution 2: Target networks

- Idea: use another Q-network and fix it in the inner loop
 - Targets don't change in the inner loop

Q-learning with replay buffer and target network. Loop:

1. save target network parameters: $\phi' \leftarrow \phi$

loop for N iterations:

- 2. collect dataset $\{(s_i, a_i, r_i, s_i')\}$ using behavior policy, add it to $\mathcal B$ loop for K iterations:
 - 3. sample a batch $\{(s_j, a_j, r_j, s_j')\}$ from buffer \mathcal{B}
 - 4. $\phi \leftarrow \phi \alpha \sum_{j} \frac{\mathrm{d}Q_{\phi}(s_{j}, a_{j})}{\mathrm{d}\phi} \left(Q_{\phi}(s_{j}, a_{j}) \left(r_{j} + \gamma \max_{a'_{j}} Q_{\phi'}(s'_{j}, a'_{j}) \right) \right)$

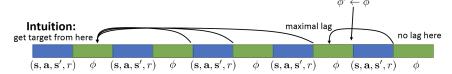

"Classic" deep Q-network (DQN)

Q-learning with replay buffer and target network. Loop:

- 1. save target network parameters: $\phi' \leftarrow \phi$
 - loop for N iterations:
 - 2. collect dataset $\{(s_i, a_i, r_i, s_i')\}$ using behavior policy, add it to \mathcal{B} loop for K iterations:
 - 3. sample a batch $\{(s_j, a_j, r_j, s_j')\}$ from buffer \mathcal{B}
 - 4. $\phi \leftarrow \phi \alpha \sum_{j} \frac{\mathrm{d}Q_{\phi}(s_{j}, a_{j})}{\mathrm{d}\phi} \left(Q_{\phi}(s_{j}, a_{j}) \left(r_{j} + \gamma \max_{a'_{j}} Q_{\phi'}(s'_{j}, a'_{j}) \right) \right)$
- Classic deep Q-learning with K = 1. Loop:
 - 1. take some action a_i and observe (s_i, a_i, s'_i, r_i) , add it to \mathcal{B}
 - 2. sample mini-batch $\{(s_j, a_j, r_j, s'_i)\}$ from \mathcal{B} uniformly
 - 3. compute $y_j = r_j + \gamma \max_{a_j'} Q_{\phi'}(s_j', a_j')$ using target network $Q_{\phi'}$
 - 4. $\phi \leftarrow \phi \alpha \sum_{j} \frac{dQ_{\phi}(s_{j}, a_{j})}{d\phi} \left(Q_{\phi}(s_{j}, a_{j}) y_{j} \right)$
 - 5. update ϕ' : copy ϕ every N steps

Alternative target network

- Classic deep Q-learning with K = 1. Loop:
 - 1. take some action a_i and observe (s_i, a_i, s'_i, r_i) , add it to \mathcal{B}
 - 2. sample mini-batch $\{(s_j, a_j, r_j, s_j')\}$ from \mathcal{B} uniformly
 - 3. compute $y_j = r_j + \gamma \max_{a_j'} Q_{\phi'}(s_j', a_j')$ using target network $Q_{\phi'}$
 - 4. $\phi \leftarrow \phi \alpha \sum_{j} \frac{dQ_{\phi}(s_{j}, a_{j})}{d\phi} \left(Q_{\phi}(s_{j}, a_{j}) y_{j} \right)$
 - 5. update ϕ' : copy ϕ every N steps
- Problem: In one inner loop, time lags for different steps are different!

Z Wang (NJU) Deep Q-learning 2025/04/21

18 / 58

Alternative target network

- Classic deep Q-learning with K=1. Loop:
 - 1. take some action a_i and observe (s_i, a_i, s'_i, r_i) , add it to \mathcal{B}
 - 2. sample mini-batch $\{(s_i, a_i, r_i, s_i')\}$ from \mathcal{B} uniformly
 - 3. compute $y_j = r_j + \gamma \max_{a_j'} Q_{\phi'}(s_j', a_j')$ using target network $Q_{\phi'}$
 - 4. $\phi \leftarrow \phi \alpha \sum_{i} \frac{dQ_{\phi}(s_{i}, a_{i})}{d\phi} (Q_{\phi}(s_{i}, a_{i}) y_{i})$
 - 5. update ϕ' : copy ϕ every N steps
- Feels weirdly uneven, can we always have the same lag?
- Popular alternative updating for the target network:

5. update
$$\phi': \phi' \leftarrow \tau \phi' + (1-\tau)\phi$$

• $\tau = 0.99$ works well

19 / 58

Deep Q-learning and fitted Q-iteration

Deep Q-learning (N = 1, K = 1). Loop:

1. save target network parameters: $\phi' \leftarrow \phi$

loop for N iterations:

- 2. collect M transitions $\{(s_i, a_i, r_i, s_i')\}$ using behavior policy, add them to \mathcal{B} loop for K iterations:
 - 3. sample a batch $\{(s_j, a_j, r_j, s_j')\}$ from buffer \mathcal{B}

4.
$$\phi \leftarrow \phi - \alpha \sum_{j} \frac{dQ_{\phi}(s_{j}, a_{j})}{d\phi} \left(Q_{\phi}(s_{j}, a_{j}) - \left(r_{j} + \gamma \max_{a'_{j}} Q_{\phi'}(s'_{j}, a'_{j}) \right) \right)$$

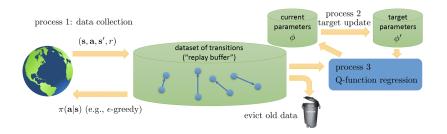

Fitted Q-iteration (written similarly as above). Loop:

- 1. collect M transitions $\{(s_i, a_i, r_i, s'_i)\}$ using behavior policy, add them to \mathcal{B} loop for N iterations:
 - 2. save target network parameters: $\phi' \leftarrow \phi$ loop for K iterations:
 - 3. sample a batch $\{(s_j, a_j, r_j, s_j')\}$ from buffer \mathcal{B}
 - 4. $\phi \leftarrow \phi \alpha \sum_{j} \frac{\mathrm{d}Q_{\phi}(s_{j}, a_{j})}{\mathrm{d}\phi} \left(Q_{\phi}(s_{j}, a_{j}) \left(r_{j} + \gamma \max_{a'_{j}} Q_{\phi'}(s'_{j}, a'_{j}) \right) \right)$

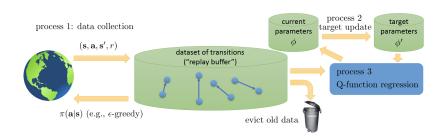

A more general view

Deep Q-learning (N = 1, K = 1). Loop:

- 1. save target network parameters: $\phi' \leftarrow \phi$
 - loop for N iterations:
 - 2. collect M transitions $\{(s_i, a_i, r_i, s_i')\}$ using behavior policy, add them to \mathcal{B} loop for K iterations:
 - 3. sample a batch $\{(s_j, a_j, r_j, s_j')\}$ from buffer \mathcal{B}
 - 4. $\phi \leftarrow \phi \alpha \sum_{j} \frac{dQ_{\phi}(s_j, a_j)}{d\phi} \left(Q_{\phi}(s_j, a_j) \left(r_j + \gamma \max_{a'_j} Q_{\phi'}(s'_j, a'_j) \right) \right)$

A more general view

- Online fitted Q-iteration: evict immediately, process 1, process 2, and process 3 run at the same speed
- DQN: process 1 and process 3 run at the same speed, process 2 is slow
- Fitted Q-iteration: process 3 is in the inner loop of process 2, which is in the inner loop of process 1

Table of Contents

- Q-learning with deep neural networks
 - Problem 1: Correlated samples Solution 1: Replay buffers
 - Problem 2: Moving target Solution 2: Target networks
- Deep deterministic policy gradient (DDPG)
 - Continuous action space
 - Approximate the optimal policy using another network
- 3 Extensions
 - Double Q-learning
 - Multi-step returns
 - Practical tips and examples

What's the problem with continuous actions?

- Full fitted Q-iteration algorithm. Loop:
 - 1. collect dataset $\{(s_i, a_i, r_i, s_i')\}$ using behavior policy π loop for K iterations:
 - 2. set $y_i \leftarrow r_i + \gamma \max_{a'_i} Q_{\phi}(s'_i, a'_i)$
 - 3. set $\phi \leftarrow \arg\min_{\phi} \sum_{i} ||Q_{\phi}(s_i, a_i) y_i||^2$
- Classic deep Q-learning. Loop:
 - 1. take some action a_i and observe (s_i, a_i, s'_i, r_i) , add it to \mathcal{B}
 - 2. sample mini-batch $\{(s_j, a_j, r_j, s_j')\}$ from \mathcal{B} uniformly
 - 3. compute $y_j = r_j + \gamma \max_{a_j'} Q_{\phi'}(s_j', a_j')$ using target network $Q_{\phi'}$
 - 4. $\phi \leftarrow \phi \alpha \sum_{i} \frac{dQ_{\phi}(s_{i}, a_{i})}{d\phi} \left(Q_{\phi}(s_{i}, a_{i}) y_{i} \right)$
 - 5. update ϕ' : copy ϕ every N steps

The target value involves the max operator

- Classic deep Q-learning. Loop:
 - 1. take some action a_i and observe (s_i, a_i, s'_i, r_i) , add it to \mathcal{B}
 - 2. sample mini-batch $\{(s_j, a_j, r_j, s'_j)\}$ from \mathcal{B} uniformly
 - 3. compute $y_j = r_j + \gamma \max_{a'_j} Q_{\phi'}(s'_j, a'_j)$ using target network $Q_{\phi'}$
 - 4. $\phi \leftarrow \phi \alpha \sum_{j} \frac{dQ_{\phi}(s_{j}, a_{j})}{d\phi} \left(Q_{\phi}(s_{j}, a_{j}) y_{j} \right)$
 - 5. update ϕ' : copy ϕ every N steps

$$\pi(a|s) = \begin{cases} 1 & \text{if } a = \argmax_a Q_{\phi}(s, a) \\ 0 & \text{otherwise} \end{cases}$$

- target value $y_j = r_j + \gamma \max_{a'_j} Q_{\phi'}(s'_j, a'_j)$
 - particularly problematic, need another inner loop of optimization
 - Question: how to perform the optimization, i.e., the max operator?

Z Wang (NJU) Deep Q-learning 2025/04/21 25 / 58

Option 1: Stochastic optimization

- The action space is typically low-dimensional
 - What about stochastic optimization?

The simplest solution: uniform sampling

- $\bullet \ \max_a Q(s,a) \approx \max\{Q(s,a_1),...,Q(s,a_n)\}$
- $(a_1, ..., a_n)$ sampled from the some distribution (e.g., uniform)

- + dead simple
- + efficiently parallelizable
- -not very accurate

More accurate solution: Cross-entropy method (CEM)

Simple iterative stochastic optimization:

- 1. Draw a sample from a probability distribution
- 2. Minimize the cross-entropy between this distribution and a target distribution to produce a better sample in the next iteration

works OK, for up to about 40 dimensions

A simple example of maximizing f(x). Loop:

- 1. Obtain N samples: $\boldsymbol{X} \sim \mathsf{SampleGaussian}(\mu, \sigma^2; N)$
- 2. Evaluate objective function f(X) at sampled points
- 3. Sort ${\pmb X}$ by $f({\pmb X})$ in descending order: ${\pmb X} \leftarrow {\sf sort}({\pmb X},f)$
- 4. Update sampling distribution by the top M elites: $\mu \leftarrow \text{mean}(\boldsymbol{X}(1:M)), \quad \sigma^2 \leftarrow \text{var}(\boldsymbol{X}(1:M))$

Objective:

$$x^* = \arg\max_{x} f(x)$$

$$\downarrow a^* = \arg\max_{a} Q(s, a)$$

Z Wang (NJU) Deep Q-learning 2025/04/21 27 / 58

Many stochastic optimization solutions...

- Covariance matrix adaptation evolution strategy (CMA-ES)
 - an evolutionary algorithm for difficult non-linear non-convex black-box optimization problems in continuous domain
- Many more solutions...

Option 2: Easily maximizable Q-functions

- Use function class that is easy to optimize
 - e.g., the quadratic function

$$Q_{\phi}(s, a) = -\frac{1}{2}(a - \mu_{\phi}(s))^{T} P_{\phi}(s)(a - \mu_{\phi}(s)) + V_{\phi}(s)$$

• NAF: Normalized Advantage Functions

$$\arg\max_{s} Q_{\phi}(s, a) = \mu_{\phi}(s)$$

$$\max_{a} Q_{\phi}(s, a) = V_{\phi}(s)$$

- + no change to algorithm
- + just as efficient as Q-learning
- loses representational power

Table of Contents

- Q-learning with deep neural networks
 - Problem 1: Correlated samples Solution 1: Replay buffers
 - Problem 2: Moving target Solution 2: Target networks
- Deep deterministic policy gradient (DDPG)
 - Continuous action space
 - Approximate the optimal policy using another network
- 3 Extensions
 - Double Q-learning
 - Multi-step returns
 - Practical tips and examples

Option 3: learn an approximate maximizer

- Lillicrap et al., "Continuous control with deep reinforcement learning," ICLR 2016.
 - Deep deterministic policy gradient (DDPG)
 - Really approximate deep Q-learning in the continuous action domain
- $\max_a Q_{\phi}(s, a) = Q_{\phi}(s, \arg \max_a Q_{\phi}(s, a))$
- ullet idea: train another network $\mu_{ heta}(s)$ such that

$$\mu_{\theta}(s) \approx \underset{a}{\arg\max} Q_{\phi}(s, a)$$

• **Question**: how to optimize this deterministic "actor" $\mu_{\theta}(s)$?

31/58

Q-learning with continuous actions

• idea: train another network $\mu_{\theta}(s)$ such that

$$\mu_{\theta}(s) \approx \underset{a}{\arg\max} Q_{\phi}(s, a)$$

• how? just solve $\theta \leftarrow \arg \max_{\theta} Q_{\phi}(s, \mu_{\theta}(s))$

$$\frac{\mathrm{d}Q_{\phi}(s,\mu_{\theta}(s))}{\mathrm{d}\theta} = \frac{\mathrm{d}Q_{\phi}}{\mathrm{d}a} \cdot \frac{\mathrm{d}a}{\mathrm{d}\theta} = \frac{\mathrm{d}Q_{\phi}}{\mathrm{d}\mu_{\theta}(s)} \cdot \frac{\mathrm{d}\mu_{\theta}(s)}{\mathrm{d}\theta}$$

new target

$$y_j = r_j + \gamma Q_{\phi'}(s_j', \mu_{\theta}(s_j')) \approx r_j + \gamma Q_{\phi'}(s_j', \operatorname*{arg\,max}_{a_j'} Q_{\phi'}(s_j', a_j'))$$

Z Wang (NJU) Deep Q-learning 2025/04/21 32 / 58

DDPG network architecture

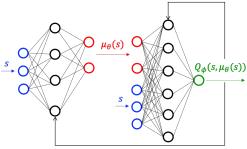

Backpropagate using Bellman error as the loss function

Backpropagate the critic:

$$\nabla_{\phi} = \frac{\mathrm{d}Q_{\phi}(s, a)}{\mathrm{d}\phi} \left(Q_{\phi}(s, a) - y \right)$$

Backpropagate the actor:

$$\nabla_{\theta} = \frac{\mathrm{d}Q_{\phi}}{\mathrm{d}\mu_{\theta}(s)} \cdot \frac{\mathrm{d}\mu_{\theta}(s)}{\mathrm{d}\theta}$$

Backpropagate using -Q as the loss function

33 / 58

Deep deterministic policy gradient (DDPG)

- Loop:
 - 1. take some action a_i and observe (s_i, a_i, s'_i, r_i) , add it to \mathcal{B}
 - 2. sample mini-batch $\{(s_j, a_j, r_j, s'_j)\}$ from \mathcal{B} uniformly
 - 3. compute $y_j = r_j + \gamma Q_{\phi'}(s'_j, \mu_{\theta'}(s'_j))$ by target networks $Q_{\phi'}$ and $\mu_{\theta'}$

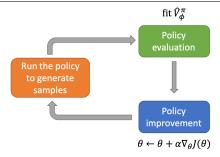

4.
$$\phi \leftarrow \phi - \alpha \sum_{j} \frac{dQ_{\phi}(s_{j}, a_{j})}{d\phi} \left(Q_{\phi}(s_{j}, a_{j}) - y_{j} \right)$$

- 5. $\theta \leftarrow \theta + \beta \sum_{j} \frac{\mathrm{d}Q_{\phi}}{\mathrm{d}\mu_{\theta}(s_{j})} \frac{\mathrm{d}\mu_{\theta}(s_{j})}{\mathrm{d}\theta}$
- 6. update ϕ', θ' : $\phi' \leftarrow \tau \phi' + (1 \tau)\phi$, $\theta' \leftarrow \tau \theta' + (1 \tau)\theta$
- The behavior policy π :
 - The target greedy policy is $\pi^*(s) = \mu_{\theta}(s)$, actually
 - Add some exploration noise to the target greedy policy, just like ϵ -greedy in tabular Q-learning

$$\pi(a|s) \sim \mathcal{N}(\mu_{\theta}(s), \sigma^2)$$

Review: Actor-critic algorithms

- Loop:
 - 1. sample $\{s_i, a_i, r_i, s_i'\}$ from $\pi_{\theta}(a|s)$ (run it on the robot)
 - 2. policy evaluation: fit $\hat{V}^{\pi}_{\phi}(s)$ to sampled reward sums
 - 3. evaluate $\hat{A}^\pi(s_i,a_i)=\hat{r_i}+\gamma\hat{V}^\pi_\phi(s_i')-\hat{V}^\pi_\phi(s_i)$
 - 4. policy improvement: $\nabla_{\theta} J(\theta) \approx \sum_{i} \nabla_{\theta} \log \pi_{\theta}(a_{i}|s_{i}) \hat{A}^{\pi}(s_{i}, a_{i})$
 - 5. $\theta \leftarrow \theta + \alpha \nabla_{\theta} J(\theta)$

DDPG vs. Actor-critic

- DDPG. Loop:
 - 1. take some action a_i and observe (s_i, a_i, s'_i, r_i) , add it to \mathcal{B}
 - 2. sample mini-batch $\{(s_i, a_i, r_i, s_i')\}$ from \mathcal{B} uniformly
 - 3. compute $y_i = r_j + \gamma Q_{\phi'}(s'_i, \mu_{\theta'}(s'_i))$ by target networks $Q_{\phi'}$ and $\mu_{\theta'}$
 - 4. $\phi \leftarrow \phi \alpha \sum_{i} \frac{dQ_{\phi}(s_{j}, a_{j})}{d\phi} \left(Q_{\phi}(s_{j}, a_{j}) y_{j} \right)$
 - 5. $\theta \leftarrow \theta + \beta \sum_{i} \frac{dQ_{\phi}}{d\mu_{\theta}(s_{i})} \frac{d\mu_{\theta}(s_{j})}{d\theta}$
 - 6. update $\phi', \theta' : \phi' \leftarrow \tau \phi' + (1 \tau)\phi, \theta' \leftarrow \tau \theta' + (1 \tau)\theta$
- Actor-critic. Loop:
 - 1. sample $\{s_i, a_i, r_i, s_i'\}$ from $\pi_{\theta}(a|s)$ (run it on the robot)
 - 2. policy evaluation: fit $\hat{V}_{\phi}^{\pi}(s)$ to sampled reward sums
 - 3. evaluate $\hat{A}^{\pi}(s_i, a_i) = r_i + \gamma \hat{V}^{\pi}_{\alpha}(s'_i) \hat{V}^{\pi}_{\alpha}(s_i)$
 - 4. policy improvement: $\nabla_{\theta} J(\theta) \approx \sum_{i} \nabla_{\theta} \log \pi_{\theta}(a_{i}|s_{i}) \hat{A}^{\pi}(s_{i}, a_{i})$
 - 5. $\theta \leftarrow \theta + \alpha \nabla_{\theta} J(\theta)$

$$Q(S_t, A_t) \leftarrow Q(S_t, A_t) + \alpha [R_{t+1} + \gamma \max_{a} Q(S_{t+1}, a) - Q(S_t, A_t)]$$

- Q-learning approximates the optimal action-value function for an optimal policy, $Q \approx Q_* = Q_{\pi_*}$
 - The target policy is greedy w.r.t Q, $\pi(a|s) = \arg\max_a Q(s,a)$
 - The behavior policy can be others, e.g., $b(a|s) = \varepsilon$ -greedy

$$Q(S_t, A_t) \leftarrow Q(S_t, A_t) + \alpha [R_{t+1} + \gamma Q(S_{t+1}, A_{t+1}) - Q(S_t, A_t)]$$

- SARSA approximates the action-value function for the behavior policy, $Q \approx Q_{\pi} = Q_{h}$
 - The target and the behavior policy are the same, e.g., $\pi(a|s) = b(a|s) = \varepsilon$ -greedy

DDPG vs. Actor-critic

DDPG

- The actor: approximate the optimal policy $a^*\mu_{\theta}(s) = \arg\max_a Q_{\phi}(s,a)$
- \bullet The critic: approximate the optimal action-value function Q_ϕ^*
- Off-policy, more sample efficient

Actor-critic

- ullet The actor: approximate the current policy $a \sim \pi_{ heta}(a|s)$
- \bullet The critic: approximate the state-value function V_ϕ^π for given policy π
- On-policy, at least converge to a local optimum

Table of Contents

 - Double Q-learning
 - Multi-step returns
 - Practical tips and examples

Overestimation in Q-learning

- ullet target value $y_j = r_j + \gamma \max_{\substack{a'_j \ ext{this is the problem}}} Q_{\phi'}(s'_j, a'_j)$
- Imagine we have two random variables: x_1 and x_2

$$\mathbb{E}[\max(x_1, x_2)] \ge \max(\mathbb{E}[x_1], \mathbb{E}[x_2])$$

- $Q_{\phi'}(s',a')$ is not perfect it looks "noisy"
- hence $\max_{a'} Q_{\phi'}(s', a')$ overestimates the next value!
- note that $\max_{a'} Q_{\phi'}(s',a') = Q_{\phi'}(s',\arg\max_{a'} Q_{\phi'}(s',a'))$
 - ullet action selected according to $Q_{\phi'}$
 - ullet value also comes from $Q_{\phi'}$

40 / 58

Double Q-learning

- $\mathbb{E}[\max(x_1, x_2)] \ge \max(\mathbb{E}[x_1], \mathbb{E}[x_2])$
- note that $\max_{a'} Q_{\phi'}(s', a') = Q_{\phi'}(s', \arg \max_{a'} Q_{\phi'}(s', a'))$
 - ullet action selected according to $Q_{\phi'}$
 - ullet value also comes from $Q_{\phi'}$
 - if the noise in the two parts is decorrelated , the problem goes away!
- IDEA: don't use the same network to choose the action and evaluate value!
- "double" Q-learning: use two networks

$$Q_{\phi_A}(s, a) \leftarrow r + \gamma Q_{\phi_B}(s', \underset{a'}{\arg\max} Q_{\phi_A}(s', a'))$$
$$Q_{\phi_B}(s, a) \leftarrow r + \gamma Q_{\phi_A}(s', \underset{a'}{\arg\max} Q_{\phi_B}(s', a'))$$

• if the two Q-networks, Q_{ϕ_A} and Q_{ϕ_B} , are noisy in different ways, there is no problem

Double Q-learning in practice

- Where to get two Q-functions?
 - just use the current and target networks!
- standard Q-learning: $y = r + \gamma Q_{\phi'}(s', \arg \max_{a'} Q_{\phi'}(s', a'))$
- double Q-learning: $y = r + \gamma Q_{\phi'}(s', \arg \max_{a'} Q_{\phi}(s', a'))$
 - just use current network (not target network) to evaluate action
 - still use target network to evaluate value

Table of Contents

n-step bootstrapping: Combine MC and one-step TD

- Neither MC or one-step TD is always the best, we generalize both methods so that one can shift from one to the other smoothly as needed to meet the demands of a particular task
- One-step TD: In many applications, one wants to be able to update the action very fast to take into account anything that has changed
- However, bootstrapping works best if it is over a length of time in which a significant and recognizable state change has occurred

n=1	n-step TD	$n = \infty$
TD(0)	\leftrightarrow	MC

n-step TD prediction

 Perform an update based on an intermediate number of rewards, more than one, but less than all of them until termination

Recall MC and TD(0) updates

• In MC updates, the target is the complete return

$$G_t = R_{t+1} + \gamma R_{t+2} + \dots + \gamma^{T-t+1} R_T$$

$$V(S_t) \leftarrow V(S_t) + \alpha [G_t - V(S_t)]$$

$$= V(S_t) + \alpha [R_{t+1} + \gamma R_{t+2} + \dots + \gamma^{T-t+1} R_T - V(S_t)]$$

In TD(0) updates, the target is the one-step return

$$G_{t:t+1} = R_{t+1} + \gamma V(S_{t+1})$$

$$V(S_t) \leftarrow V(S_t) + \alpha [G_{t:t+1} - V(S_t)]$$

$$= V(S_t) + \alpha [R_{t+1} + \gamma V(S_{t+1}) - V(S_t)]$$

n-step TD update rule

• For *n*-step TD, set the target as the *n*-step return

$$G_{t:t+n} = R_{t+1} + \gamma R_{t+2} + \dots + \gamma^{n-1} R_{t+n} + \gamma^n V(S_{t+n})$$

 All n-step returns can be considered approximations to the complete return, truncated after n steps and then corrected for the remaining missing terms by $V(S_{t+n})$

$$V(S_t) \leftarrow V(S_t) + \alpha [G_{t:t+n} - V(S_t)]$$

= $V(S_t) + \alpha [R_{t+1} + \gamma R_{t+2} + \dots + \gamma^{n-1} R_{t+n} + \gamma^n V(S_{t+n}) - V(S_t)]$

Deep Q-learning 2025/04/21 47 / 58

Deep Q-learning with *n*-step bootstrapping

- \bullet Q-learning target: $y_{j,t} = {\color{red} r_{j,t}} + \gamma {\max_{a'_{j,t+1}} Q_{\phi'}(s'_{j,t+1}, a'_{j,t+1})}$
 - ullet these are the only values that matter if $Q_{\phi'}$ is bad!
 - ullet these values are important if $Q_{\phi'}$ is good
- ullet Construct multi-step targets, N-step return estimator:

$$y_{j,t} = \sum_{t'=t}^{t+N-1} \gamma^{t'-t} r_{j,t'} + \gamma^N \max_{a'_{j,t+N}} Q_{\phi'}(s'_{j,t+N}, a'_{j,t+N})$$

Simple practical tips for Q-learning

- Q-learning takes some care to stabilize
 - Test on easy, reliable tasks fist, make sure your implementation is correct

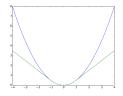

Figure: From T. Schaul, J. Quan, I. Antonoglou, and D. Silver. "Prioritized experience replay". arXiv preprint arXiv:1511.05952 (2015), Figure 7

- Large replay buffers help improve stability
 - Looks more like fitted Q-iteration
- It tasks time, be patient might be no better than random for a while
- Start with high exploration and gradually move to high exploitation

Advanced tips for Q-learning

Bellman error gradients can be big; clip gradients or use Huber loss

$$\mathcal{L}(x) = \begin{cases} x^2/2 & \text{if } |x| \leq \delta \\ \delta |x| - \delta^2/2 & \text{otherwise} \end{cases}$$

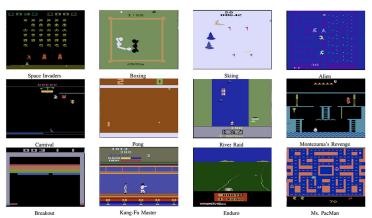

- Double Q-learning helps a lot in practice, simple and no downsides
- N-step returns also help a lot, but have some downsides
- Schedule exploration (high to low) and learning rates (high to low)
 - Adam optimizer can help too
- Run multiple random seeds, it's very inconsistent between runs

Deep Q-learning 2025/04/21 51/58

Q-learning with convolutional networks

- Mnih et al., "Human-level control through deep reinforcement learning," 2013.
- Use replay buffer and target network
- One-step backup, one gradient step
- Can be improved a lot with double Q-learning (and other tricks)

52 / 58

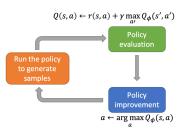

Q-learning on a real robot

- Gu et al., "Robot manupulation with deep reinforcement learning and ...," 2017.
- Continuous actions with NAF (quadratic in actions)
- Use replay buffer and target network
- One-step backup, four gradient steps per simulator step for efficiency
- Parallelized across multiple robots

Review

Learning objectives of this lecture

- You should be able to...
 - Use deep neural networks to approximate Q-functions, be able to implement deep Q-learning with replay buffers and target networks
 - Use deep deterministic policy gradient for continuous actions
 - Know double Q-learning for addressing the overestimation problem
 - Know deep Q-learning with *n*-step returns
